Table S2. List of PDS distance restraints for Rosetta modeling.

Fig. S1. Preliminary purification and characterization of receptor foldons and their complexes. (A) Subunit fusion and linker design of the foldons. The foldons were engineered to produce a pre-formed trimer-of-(single-chain)-dimer arrangement. Receptor regions surrounding the protein interaction regions (PIRs) of the receptor cytoplasmic domains were fused to form a single-chained dimer that is capped with an N-terminal trimerization motif from T4-phage fibritin. (B) SEC-MALS trace of the Tar foldon; MW $(60 \mathrm{kDa})$ matches expectations for a trimer (C) SEC-MALS trace of TarFO with Thermotoga maritima (Tm) CheA and CheW produces high molecular-weight complexes. (D) SEC-MALS trace of the Tm14 foldon; MW 60 kDa also corresponds to a trimer-of-single-chain-dimers and (E) SEC-MALS trace of Tm14 FO with Tm CheA and CheW.

Fig. S2. Buffer conditions that encourage interactions among TarFo, CheA and CheW. (A) The foldons primarily form two particles in solution: MW $=250 \mathrm{kDa}$ or MW $=320 \mathrm{kDa}$, the latter consistent with the size of a core signaling unit. (B) SEC-MALS traces of ternary complexes under various buffer conditions. Larger complexes ( 320 kDa ) are present with KCl and lower pH .

Fig. S3. Properties of the Tm14Fo complexes with Tm CheA and Tm CheW. (A) Size-exclusion chromatography of a mixture of Tm14 foldon with CheA and CheW produces two high-molecular weight peaks (denoted 1 and 2). (B) SEC-MALS experiments with complexes in Peak 1 denote particles of MW that corresponds to four CheA subunits, 4 CheW subunits and two receptor foldons. SEC-MALS of Peak 2 indicates that the particles consist of one CheA dimer with two CheW subunits and one receptor foldon. (C) ${ }^{32}$ P-ATP initial autophosphorylation activity of free CheA and complexes 1 and 2. Data taken at 3-6 min when product accumulation is linear. Mean values $\pm \mathrm{s}$ shown for $\mathrm{N}=4$ ( $\mathrm{P}<0.05, * * \mathrm{P}<0.01$, oneway ANOVA, Tukey post hoc comparison). The 450 kDa complex deactivates CheA $\sim 3$ fold and the 220 kDa complex deactivates CheA $\sim 1.5$ fold; CheA subunit concentration was kept constant. (D) SEC-SAXS derived molecular envelope of the complexes in Peak 1 superimposed with a complex of TarFO:CheA(P3P4P5):CheW based on crystal structures and array models to gauge spatial extent. (E) Negative-stain electron microscopy of particles in Peak 1 shows monodispersed particles of around $100 \AA$ in diameter. Black scale bar is 100 nm .

Fig. S4. Autoradiographs of the CheA autophosphorylation experiments from Fig. 1. (A) Radioisotope assays with Ec CheA. Assays performed in parallel and imaged together for comparison of CheW-dependent activation of free Ec CheA and Ec CheA in signaling units. (B) Radioisotope assays with Tm CheA.

Fig. S7. Inter-domain cross-links in free CheA. Cross-linked peptides in yellow are found in the free kinase, but not the foldon complex. For individual domains, distancs are given for intra-subunit separations between Lysine residues ( $\mathrm{Cb}-\mathrm{to}-\mathrm{Cb}$ ) as found in the noted crystal or NMR Protein Data Bank structures. In the case of P3, asterisks indicate the inter-subunit distance of the dimer. For cross-links between domains, the closest distance in the respective crystal structures are shown.

Fig. S8. Inter-domain cross-links in the receptor foldon complex. Cross-linked peptides in yellow are found in the foldon complexes, but not the free kinase. For individual domains, distancs are given for intra-subunit separations between Lysine residues $(\mathrm{Cb}-\mathrm{to}-\mathrm{Cb})$ as found in the noted crystal or NMR Protein Data Bank structures. In the case of P3, asterisks indicate the inter-subunit distance of the dimer. For cross-links between domains, the closest distance in the respective crystal structures are shown

Fig. S9. PDS of Tm CheA E588C-R1 with CheW and TarFo. Base-line corrected time domain data (left) before (red) and after (black) wavelet denoising and resulting distance distributions (right, black) with error bounds (red). Schematic shows known CheA self-association through its P5 domains in a manner that would bring opposing 588C-R1 sites in close proximity (shown by red dots in the schematic). In absence of other spin sites, the close 588C-R1 positions dominate the PDS signal.

Fig. S10. Modeling of the foldon complex. (A) Overlay of $\mathrm{C} \alpha$ traces representing conformations sampled in Rosetta under constraints from PDS and cross-linking. Conformations were evaluated for their agreement with SAXS data and low Rosetta energy scores. (B) Conformational models generated by considering flexibility of L4. The highest scoring model in (A) was subjected to loop perturbation about the P4-P5 hinge (L4), while treating P5-CheW-receptor foldon units as rigid units on each CheA subunit, and then subsequently evaluated against the SAXS data. (C) Highest scoring model $\left(\mathrm{X}^{2}=4.5\right)$ fit to the solution x-ray scattering data.

Fig. S11. Summary of model restraints in Rosetta refinements. Restraints are derived from PDS measured distances and unique DSSO cross-links formed in the foldon-receptor complexes. Model 10 represents the model with the lowest Rosetta energy (-5863 Rosetta Energy Units (REUs)); model 41 represents the model with the closest agreement to the SAXS data (-5680 REU).
